ABSTRACT

The species composition and distribution of the pseudothelphusid and trichodactylid freshwater crabs from the state of Roraima, Brazil, are updated based mainly on documented records deposited in the collections of the Instituto Nacional de Pesquisas da Amazônia (Manaus) and the Museu Integrado de Roraima (Boa Vista). This paper provides records for the occurrence of ten species (six Pseudothelphusidae, four Trichodactylidae). Three species are recorded from Roraima for the first time: the pseudothelphusids *Fredius beccarii* (Coifmann, 1939) and *Fredius fittkauai* (Bott, 1967), and the trichodactylid *Moreirocarcinus laevifrons* (Moreira,

1901). The records of *F. beccarii* also represent the first documented occurrence of the species in Brazil. All species in the state are presented in maps that document their geographic distribution. Comments are made on the diversity of the Branco River crab fauna in comparision with diversity in other sub-basins of the Amazon River.

KEY WORDS

Amazon region, geographic distribution, Guyana Shield, Neotropical region, new record.

INTRODUCTION

The Brazilian state of Roraima is situated in the northern limits of the Amazon Basin. Despite its small territory ($225,116 \text{ km}^2$), Roraima is ecologically diversified due to marked differences in climate, vegetation, geomorphology, landscape and river drainages (Barbosa *et al.*, 1997; Ferreira *et al.*, 2007). Magalhães and Pereira (2007) listed ten pseudothelphusid and eight trichodactylid species of crabs for the whole Negro River basin, which, covering $700,000 \text{ km}^2$, comprises the third largest tributary area of the Amazon drainage, and 10.1% of the whole Amazon basin (Goulding *et al.*, 2003). The Branco River, which is the largest sub-basin in the Negro River, drains most of Roraima's territory and yet its freshwater crab fauna is not well known. To date, seven species have been recorded from the state, based on few, sporadic samples. Magalhães (1986) documented the occurrence of the pseudothelphusid, *Kingsleya latifrons* (Randall, 1840), and Magalhães and Türkay (1996b; 2008a) recorded two species of trichodactylids: *Syliocarcinus pictus* (H. Milne Edwards, 1853) and *Poppiana dentata* (Randall, 1840), respectively. These same records were used by Magalhães (1998; 2003) for contributions to a catalogue and the manual for the identification of Brazilian crustaceans, respectively. More recently, Castro and Silva (2013) extended the distribution of the trichodactylid crab, *Valdivia serrata* White, 1847, to the state of Roraima. Magalhães *et al.* (2014) listed *Fredius estevisi* Rodriguez, 1966, *Fredius platyacanthus* Rodríguez and Pereira, 1992, and *Fredius stenolobus* Rodríguez and Suárez, 1994 as species collected in Roraima among species used for comparison in a molecular study. Magalhães and Pereira's (2007) inventory of the Negro River basin included the published records (Magalhães, 1986; Magalhães and Türkay, 1996) and some unpublished records at the time for *F. estevisi*, *F. platyacanthus*, *F. stenolobus*, and *P. dentata* (CM, pers. obs.) in their compilation.

Carcinological surveys made during the last decade in several areas throughout the state revealed that its freshwater crab fauna is more diverse and widespread than currently known. The purpose of this paper is to document the occurrence and distribution of several species of both pseudothelphusid and trichodactylid crabs in Roraima, and to extend the range of distribution of some of these species into the Amazon River basin in Brazil.

MATERIAL AND METHODS

Study area

Roraima is the northernmost of the Brazilian states, located between the geographic coordinates **05°16'N** and **01°25'S**, and **058°55'W** and **64°48'W**, and bordered by Venezuela in the west and north, and Guyana in the east (Ferreira *et al.*, 2007). The hydrographic system is dominated by the Branco River, whose watershed covers $187,540 \text{ km}^2$, comprising 83% of the state territory (Carvalho, 2015). The river is formed by the confluence of the Uraricoera River and Tacutu River and flows northeast-southwest for 566 km. Other main rivers are the Xeruini and Jauaperi Rivers (tributaries of the Negro River), and Jatapu River (tributary of the Amazon River), all located in the south and southeastern portion of the state (Santos *et al.*, 1985; Ferreira *et al.*, 2007; Carvalho, 2015). Roraima is situated within the boundaries of the Guyana Shield region as defined in Huber (1995) and in the Remarks and Discussion sections we use the hydrologic limits of the region as defined in Lujan and Armbruster (2011: 212, fig. 13.1).

Data collection

The specimens were obtained either from field surveys, conducted in several localities throughout the state between April 2014 and April 2015, or from material deposited in the collections of the Instituto

Nacional de Pesquisas da Amazônia, Manaus (INPA), Instituto Venezolano de Investigaciones Científicas, Caracas (IVIC), Museu Integrado de Roraima, Boa Vista (MIRR), Museu Nacional, Universidade Federal do Rio de Janeiro, Rio de Janeiro (MNRJ), Museu de Zoologia, Universidade de São Paulo, São Paulo (MZUSP), and Universidad Nacional Autónoma de México, Colección Nacional de Crustáceos, Mexico City (CNCR). Fresh material was fixed in 90% ethanol, preserved in 70% ethanol, and deposited in the INPA collection. All sampling was done according to the permit issued by IBAMA (SISBIO # 44857-1).

Taxonomic and distributional analysis

The taxonomic identification was carried out using the keys, descriptions and illustrations available in Magalhães (1986; 2003) and other pertinent publications when necessary (Magalhães and Türkay, 1996a; 1996b; 1996c; 2008; Magalhães and Rodríguez, 2002; Magalhães, 2010), as well as by comparison with identified material in the INPA collection. Suprageneric classification follows Ahyong *et al.* (2011), and the taxa are organized alphabetically. The distribution maps were generated using the QGIS software, v. 2.14.16 (http://www.qgis.org/pt_BR/site/), following the instructions presented in the second part of the tutorial by Calegari *et al.* (2016). The geographic coordinates of each record were obtained either from a GPS apparatus during sampling or from data on the labels of the collection lots. When coordinates were unavailable, the localities were georeferenced using Google Earth® software and online gazetteers (GeoNames: <http://www.geonames.org/>) and these are noted between parentheses; those coordinates informed between brackets represent the municipality seat, since the locality could not be determined with reasonable accuracy. To generate the maps, the coordinates were all converted to decimal degrees using WGS84 datum (the same datum used in the GPS receiver employed during sampling), according to the calculator provided by the Instituto Nacional de Pesquisas Espaciais (<http://www.dpi.inpe.br/calcula/>).

Conventions

Measurements of the crab carapace are in millimeters when they are available; carapace width was measured across the carapace at its widest point, and carapace

length was measured along the midline, from the frontal to the posterior margin. Both measurements follow the number and sex of the specimens examined and are given between parenthesis as (carapace width:carapace length); in lots with more than three species, only the measurements of the smallest and the largest specimens are informed. G1 refers to the first male gonopod. Abbreviations used are: "ad." for adult(s); "elev." for elevation; "immat." for immature specimen; "juv." for juvenile(s); "mun." for municipality, "ov." for ovigerous; "trib." for tributary. In 'Material examined' the names of geographic elements were kept as written in Portuguese on the original labels and mean: cachoeira = falls; fazenda = farm; igarapé = small river, stream; lago = lake; PARNA = National Park; praia = beach; PIN = Posto Indígena (Indigenous Health Post); rio = river; serra = mountain range; sítio = small farm; vicinal = side road; vila = village. The names of some landforms, particularly those in the Brazilian territory, were written according to the spelling in Portuguese.

RESULTS

The total number of freshwater crab species known in the state of Roraima increased to ten: six Pseudothelphusidae and four Trichodactylidae. Three species are recorded from Roraima for the first time: the pseudothelphusids *Fredius beccarii* (Coifmann, 1939) and *Fredius fittkaui* (Bott, 1967), and the trichodactylid *Moreirocarcinus laevifrons* (Moreira, 1901). The records of *F. beccarii* also represent the first occurrence of the species in Brazil.

Pseudothelphusidae Ortmann, 1893

Genus *Fredius* Pretzmann, 1967

***Fredius beccarii* (Coifmann, 1939)** (*Figs. 1A, 3*)

Material examined. BRAZIL, Roraima: 1 male (40.2:26.4), MIRR 95, mun. Amajarí, Tepequém, RR 203 road, igarapé Pau Baru, 03°41'N 061°41'W, 24.ii.2011, F. Zanetti, A.A. Otaviano, A.S. Sales and D. Teixeira; 1 male (35.7:23.8) 1 female (33.2:22.4), INPA 1895, mun. Amajarí, vila Bom Jesus, vicinal II, Trairão, igarapé Coimbra, 03°37'N 061°49'W, 24.ii.2011, F. Zanetti, A.A. Otaviano, A.S. Sales and

D. Teixeira, F.C. Zanetti, A.A. Otaviano, A.S. Sales and Neiva; 3 males (29.2:19.9–43.5:28.9), 7 females (27.7:19.4–88.1:57.4), INPA 2435, mun. Amajari, vila Bom Jesus, vicinal II, Trairão, igarapé do Coimbra, 03°37'N 061°49'W, 18.iv.2015, F. Zanetti and M.A.L. Santos; 2 males (21.2:14.9; 32.9:22.5) 1 young, MIRR 97, mun. Amajari, vila Bom Jesus, vicinal II, Trairão, igarapé Coimbra, 03°37'N 061°49'W, 31.x.2009, F. Zanetti, P.M. Castro and D.A. Lima.

Distribution. Venezuela, Guyana, and Brazil [new record] (Roraima) (Rodríguez, 1982; this study).

Remarks. The G1s of our specimens (Fig. 1A) are morphologically very similar to that of a specimen from the Rupununi River, in Guyana, figured by Rodriguez (1982: 135, fig. 129).

Until now, the species was known from eastern Venezuela and Guyana in the Essequibo River

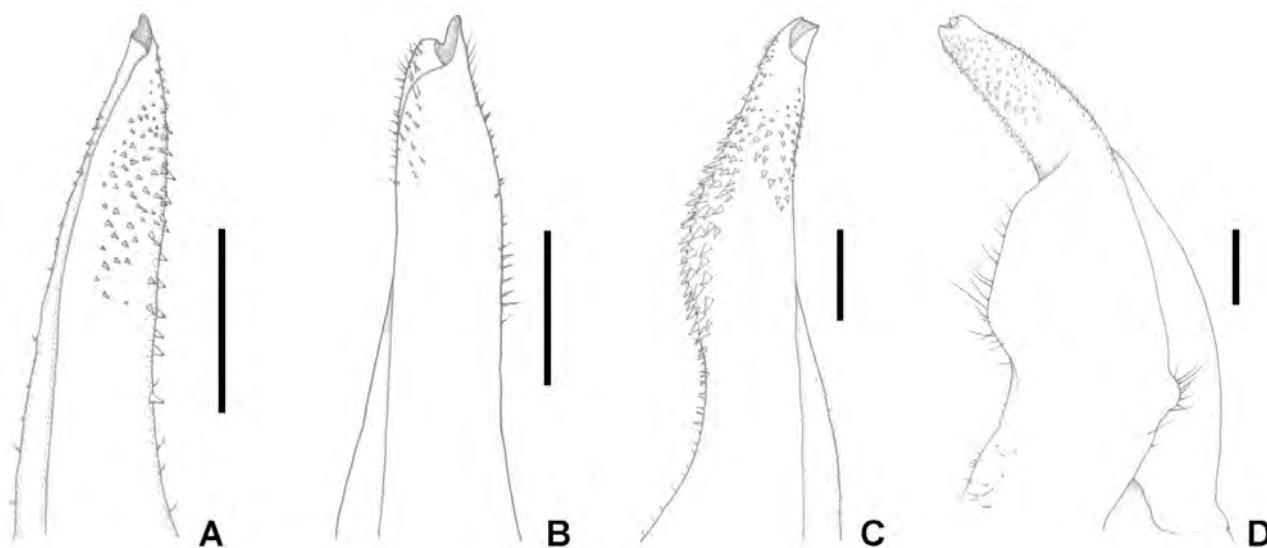

Figure 2. Male first gonopod, right side, of the trichodactylid crabs from Roraima. A, *Moreirocarcinus laevifrons* (Moreira, 1901), distal part, mesial view, INPA 1493; B, *Poppiana dentata* (Randall, 1840), distal part, mesial view, INPA 1896; C, *Sylviocarcinus pictus* (H. Milne Edwards, 1853), distal part, mesial view, INPA 1900; D, *Valdivia serrata* White, 1847, whole limb, mesio-caudal view, INPA 1505.

and Demerara River basins (Rodriguez, 1982). Its occurrence in the Uraricoera River basin indicates that the species can be found in both the northern and southern slopes of the Guyana Shield (Fig. 3).

***Fredius estevisi* (Rodriguez, 1966)**
(Figs. 1B, C, 3)

Previous records. Magalhães and Pereira (2007: 124, in table 4 - listed under Negro River basin); Magalhães et al. (2014: 104, in table, 105).

Material examined. BRAZIL, Roraima: 3 males (2 immat.), 5 females (4 juv.), 4 youngs, INPA 2436, mun. Pacaraima, headwaters of rio Miang, 04°29'N 061°07'W, 13.vi.2014. F. Zanetti, M.A.L. Santos, Farias, R.E.S., S.C. Emidio and F.R. Silva; 5 males, 8 females, INPA 2434, mun. Pacaraima, headwaters of rio Miang, 04°29'N 061°07'W, 24.i.2015. F. Zanetti, S.C. Emidio and T.E. Souza; 1 male (78.2:50.1) 2 females (64.2:40.1; 79.9:51.6), INPA 839, Yanomami Indigenous Reserve, igarapé Inajá, trib. of rio Parima, rio Uraricoera basin, PIN Parafuri, 03°17'59"N 064°00'30"W, 22.iv.1994, leg. L.S. Aquino and U.C. Barbosa.

Distribution. Venezuela and Brazil (Roraima) (Rodriguez and Pereira, 1992; Magalhães et al., 2014).

Remarks. Rodriguez and Pereira (1992) described a new subspecies, *F. estevisi siapensis* Rodríguez and Pereira, 1992, and distinguished it from the nominal subspecies by the mesial lobe of the G1, presenting “the proximal margin concave and the distal margin regularly arched”, giving it a thumb-like appearance, whereas the nominal subspecies has a mesial lobe with proximal and distal margins more or less straight, showing a conical shape. The specimens from Roraima have a G1 with mesial lobe bearing a conical appearance (Fig. 1B, C) and are therefore assigned to the nominal species. Besides, the localities of the Roraima specimens (particularly those of the Miang River) (Fig. 3) are not geographically distant from the localities in the upper Caroni River presented by Rodriguez and Pereira (1992). According to these authors, the nominal form is distributed in the southeastern portion of the state of Bolívar, in the “Gran Sabana” region, mainly in tributaries of the upper Caroni River coming from the slopes of Mount Roraima and draining to the Orinoco River Basin, while *F. estevisi siapensis* occurs in the Siapa and Cunucunuma Rivers, in the Venezuelan state of Amazonas.

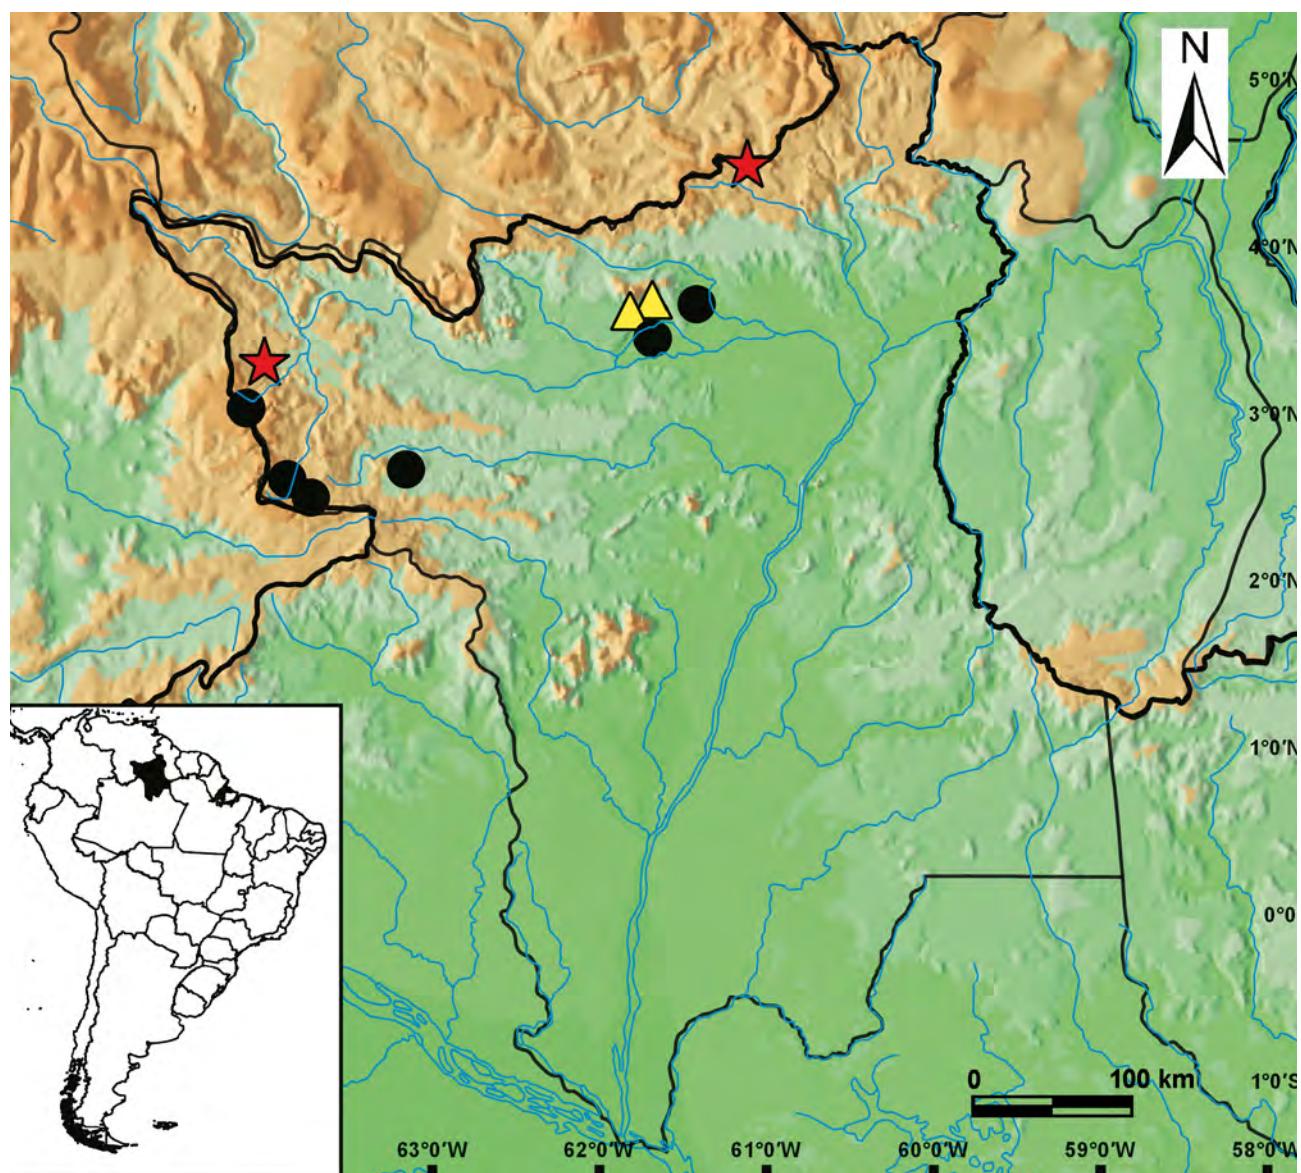

Figure 3. Distribution of the pseudothelphusid species, *Fredius beccarii* (Coiffmann, 1939) (triangle), *F. estevisi* (Rodríguez, 1966) (star), and *F. platyacanthus* Rodriguez and Pereira, 1992 (circle), in the state of Roraima, Brazil.

***Fredius fittkaui* (Bott, 1967)**
(Figs. 1D, 4)

Distribution. Venezuela, Guyana, Brazil (Amazonas, Roraima [new record]) (Magalhães and Rodríguez, 2002; this study).

Material examined. BRAZIL, Roraima: 1 male (69.7:45.6), 1 female (64.0:41.5), INPA 2440, mun. Uiramutá [04°35'59"N 060°09'29"W], rio Cambarú, Maturucá indigenous village, 02.iii.2015, S. Silva; 4 immat. males (22.9:14.6–27.6:17.4), INPA 1338, Yanomami Indigenous Reserve, Rio Uxua-ú, PIN

Homoxi, 02°29'51"N 063°43'47"W, 15.xi.2003, V. Py-Daniel and U.C. Barbosa.

Remarks. The G1s of the Roraima specimens (Fig. 1D) have all the morphological features as described for the G1 of the upper Negro River specimens by Magalhães and Rodríguez (2002): the well-developed, curved cephalic spine with a rounded tip; and an auxiliary lobe situated laterally and shorter than the cephalic lobe.

Fredius fittkaui has a disjunct distribution, occurring in the southwestern limits of the Guyana Shield in

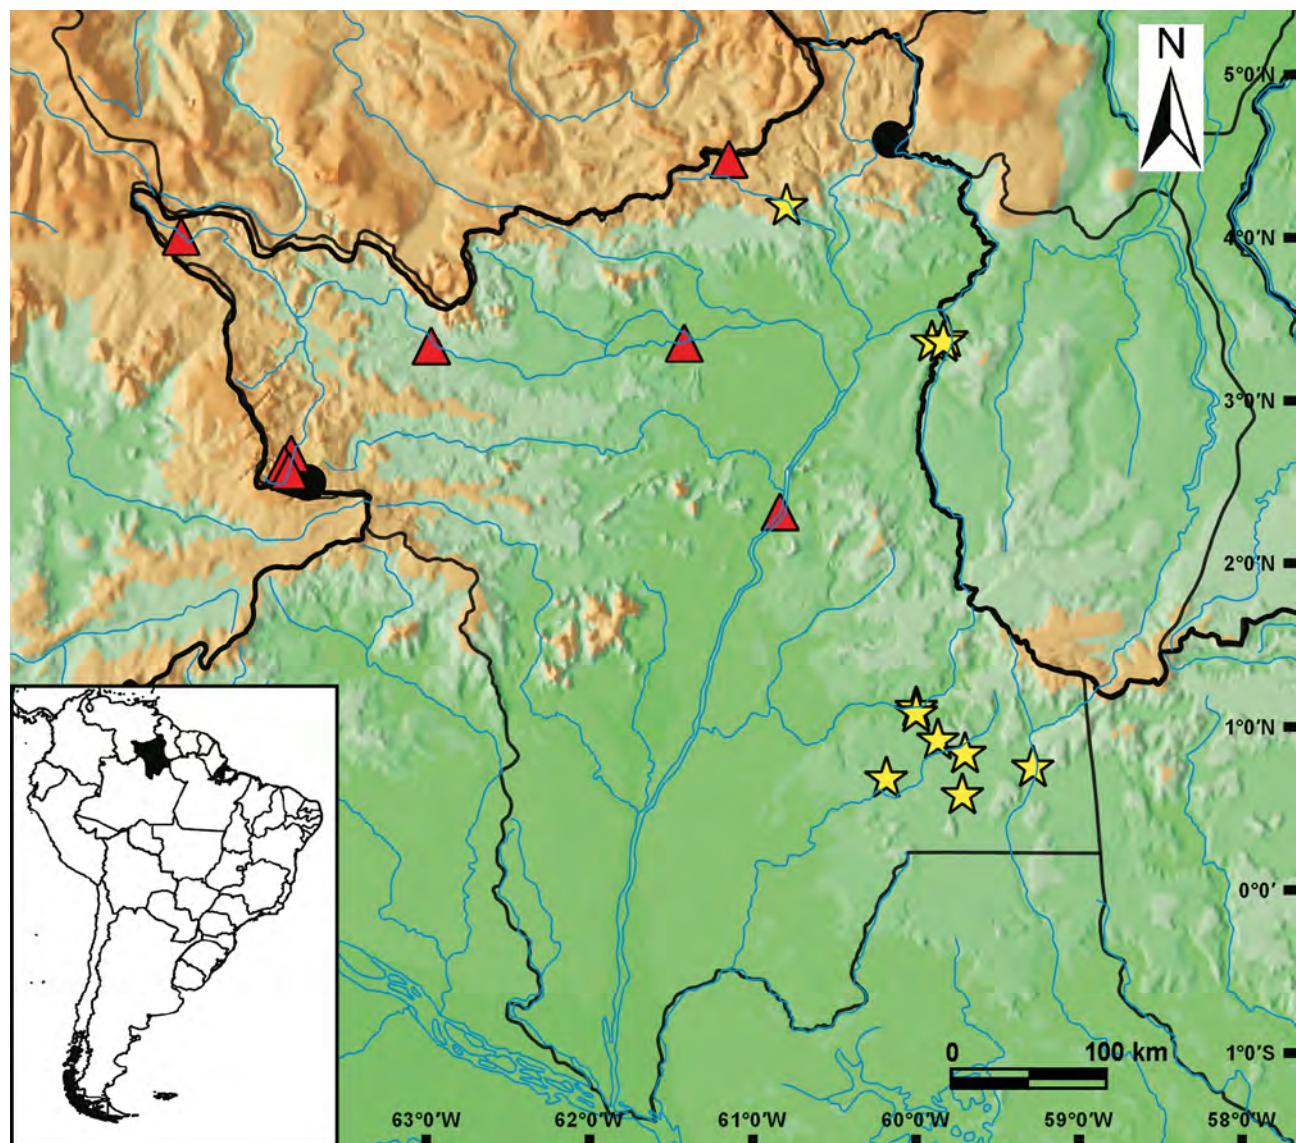

Figure 4. Distribution of the pseudothelphusid species, *Fredius fittkaui* (Bott, 1967) (circle), *F. stenolobus* Rodríguez and Suárez, 1994 (triangle), and *Kingsleya latifrons* (Randall, 1840) (star), in the state of Roraima, Brazil.

Brazil and Venezuela (with several records in northern tributaries of the upper Negro River), and in Guyana (Magalhães and Rodríguez, 2002). Unfortunately, the sole record available from Guyana lacks indication of a precise locality (Magalhães and Rodríguez, 2002). The present two records in the state of Roraima (Fig. 4) indicate that the species may have a continuous distribution along the tributaries of the Negro River and Branco River that drain the southern slopes of the Guyana Shield, probably reaching Guyana through the lowland areas along the Tacutu and upper Rupununi Rivers (see also Magalhães and Rodríguez, 2002: 687, fig. 4).

Fredius platyacanthus

Parima basin (trib. of rio Uraricoera), rio Kanaakiú, PIN Xitei/Xidea, 02°36'29"N 063°52'18"W, 780 m elev., 03.vii.1995, V. Py-Daniel *et al.*; 1 male (54.1:33.1), INPA 840, mun. Alto Alegre, Yanomami Indigenous Reserve, rio Parima basin (trib. of rio Uraricoera), igarapé das Irmãs, cachoeira Grande, PIN Xitei/Xidea, 02°36'24"N 063°52'17"W, 750 m elev., 24.vi.1997, V. Py-Daniel *et al.*; 1 male (32.1:21.4), INPA 1337; 1 male (69.8:44.3), 2 females (92.1:57.6; 100.7:63.3), INPA 1329, mun. Alto Alegre, rio Uxua-ú, PIN Homoxi, 02°29'51"N 063°43'47"W, 15.xi.2003, U. Barbosa.

Remarks. The G1s of the specimens studied herein (Fig. 1E, F) have the mesial process wide, with proximal margin distinctly convex in mesio-caudal

view, and ending in a bifid tip; cephalic lobe auricular in latero-cephalic view, auxiliary lobe slightly shorter than cephalic one, with caudal border bearing small cephalic spine; field of apical spine well developed, wide, longitudinally situated along the latero-cephalic side. These features highly resemble those of the G1 of the holotype of *F. platyacanthus* that was figured by Rodriguez and Pereira (1992: 305, fig. 3), but some variations can be noticed: the cephalic lobe is a little shorter than the mesial process in the Roraima specimens (even considering the angle from which the illustration was made), and the cephalic spine is a bit smaller than that of the holotype.

Fredius platyacanthus was only known from the male holotype collected in the Icabaru River, a left bank

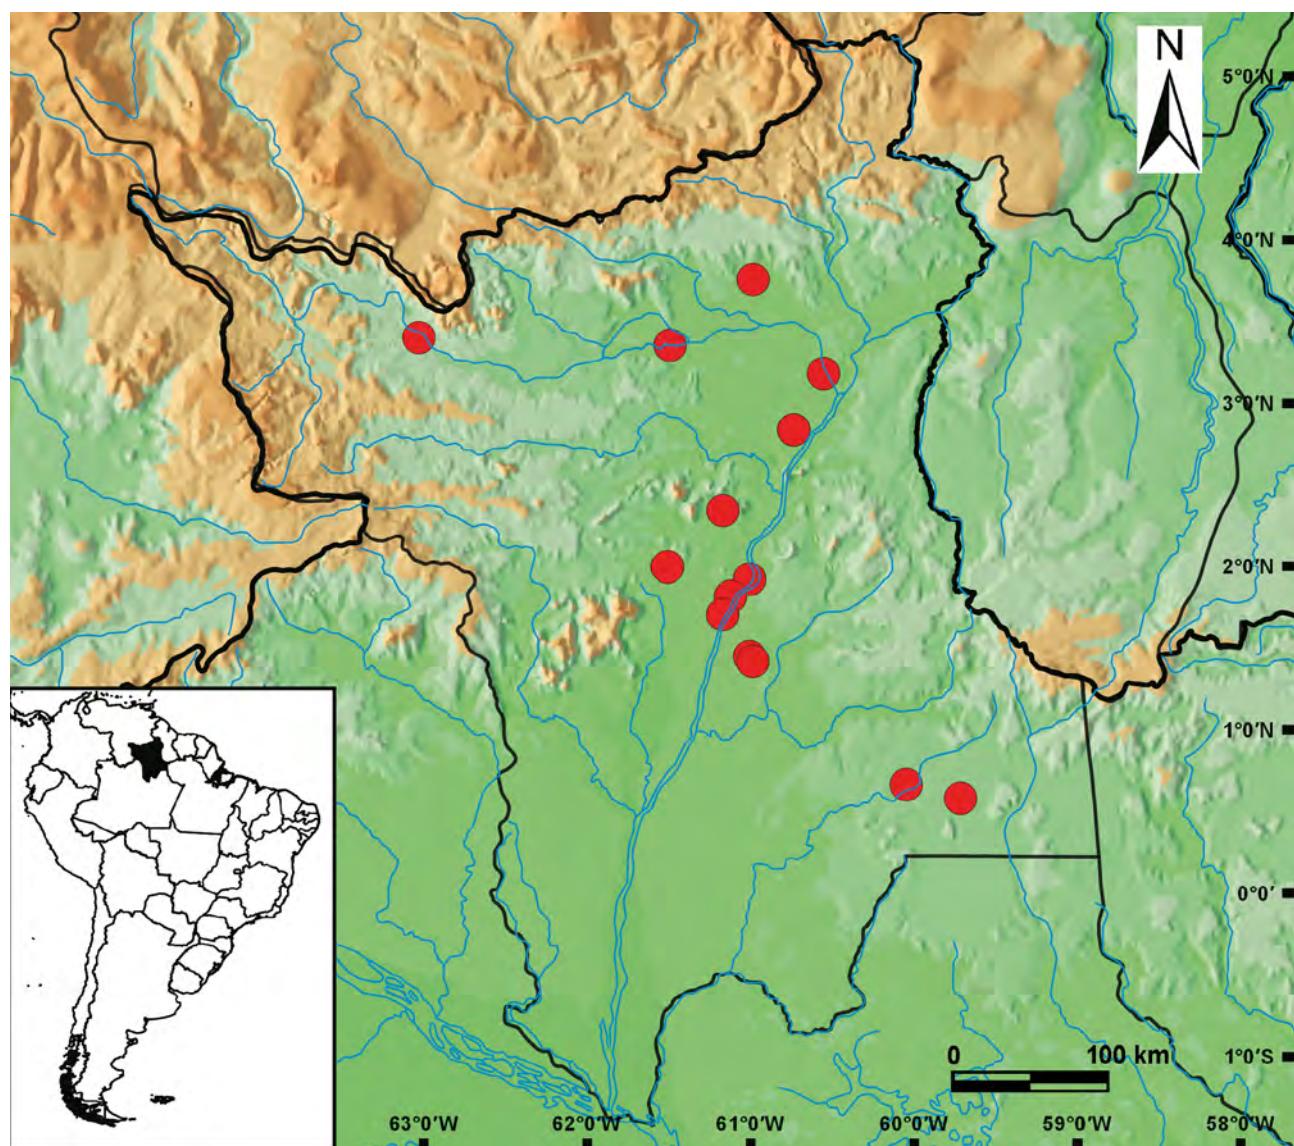

Figure 7. Distribution of the trichodactylid species, *Valdivia serrata* White 1847, in the state of Roraima, Brazil.

tributary of the upper Caroni River, in the Orinocoan slopes of the Serra Pacaraima. The several records presented above indicate that the species is more widely distributed on the Amazonian slopes of the Guyana Shield. In addition to the records from the upper and middle course of the Uraricoera River (Fig. 3), Magalhães *et al.* (2006) recorded the species from the Yanomami village of Balawa-ú, in the state of Amazonas, Brazil, in the headwaters of the Demini River, a left tributary of the Negro River (the authors erroneously noted it as *Fredius reflexifrons* (Ortmann, 1897) in tab. 1).

At the moment, we prefer to consider our material as co-specific with the *F. platyacanthus*' type, since a more precise assessment of the variability of these

G1's features is not possible without examining a more abundant series of specimens from the upper Caroni River area.

Py-Daniel *et al.*; 1 male (76.5:48.7), INPA 1247, rio Branco, rocky area downstream from the mouth of rio Mucajá (02°19'00"N 060°50'00"W), 11.iv.1997, leg. V. Kowalcuk.

Distribution. Venezuela, Brazil (Roraima) (Rodríguez and Suárez, 1994; Mora-Day and Blanco-Belmonte, 2008; this study).

Remarks. The gonopods of the specimens from Roraima (Fig. 1G) show a high morphological similarity with that of the holotype as described in Rodríguez and Suárez (1994) and figured in Rodríguez

and Campos (1998: 766, fig. 2A, B) and no remarkable variation was noticed.

With the present records, *F. stenolobus* exhibits a somewhat wide distribution that encompasses both the Amazonian and Orinocoan slopes of the Serra Paracarima. On the Venezuelan side, the species is distributed in the contiguous hydrographic basins of the Caura River (Rodríguez and Suárez, 1994; Magalhães and Pereira, 2003) and in the Paragua River (Mora-Day and Blanco-Belmonte, 2008). On the Brazilian side, it seems to be relatively frequent in the more elevated areas (above 750 m) of the upper Uraricoera River and upper Surumu River basins, but also occurring at lower elevations in the middle course of the Branco River after its confluence with the Mucajá River (lower than 100 m) (Fig. 4).

Genus *Kingsleya* Ortmann, 1897

Kingsleya latifrons (Randall, 1840) (Figs. 1H, 4)

Previous records. Magalhães (1986: 615); Magalhães (1998: 518, in catalogue); Magalhães (2003: 184, in map); Magalhães and Pereira (2007: 123, in table 3 - listed under Amazon basin, 124, in table 4 - listed under Negro River basin).

Material examined. BRAZIL, Roraima: 2 males (51.0:33.0; 52.0:33.3), 2 females (57.0:36.8; 65.3:41.2), MZUSP 6390, Surumu (04°11'35"N 060°47'35"W), date and leg. unknown; 1 male (42.0:25.9), INPA 1248, mun. Bonfim, rio Tacutu (03°22'51"N 059°48'40"W), 26.i.1992, J. Zuanon and J.A. Gomes; 1 male (31.4:20.7) 1 female (24.6:16.0), INPA 1249, mun. Bonfim, igarapé Arraia, approximately 8 km before Bonfim, under the bridge (03°21'21"N 059°54'13"W), 25.i.1992, J. Zuanon; 1 male (53.9:34.0), 2 females, MIRR 75, mun. Bonfim, urban center, rio Tacutu (03°21'20"N 059°49'51"W), 12.iii.2011, P.R.P. Andrade; 2 males, 7 females, INPA 2430) mun. Bonfim, urban center, rio Tacutu (03°21'14.8"N 059°49'57.4"W), 07.iv.2015, F. Zanetti and S.C. Emídio; 4 males, 3 females, INPA 2433, mun. São Luiz do Anauá, rio Anauá, vicinal 21 (01°07'N

060°00'W), 31.i.2015, F. Zanetti, M.A.L. Santos; I.R. Almeida and S.C. Emidio; 3 males, 6 females (1 ov.), INPA 2439, mun. São Luiz do Anauá, igarapé São Luizão, vicinal 21 (01°05'N 060°00'W), 31.i.2015, F. Zanetti, M.A.L. Santos, I.R. Almeida and S.C. Emidio; 2 males, 1 female, INPA 2436, mun. São João da Baliza, vicinal 28, unnamed igarapé (00°55'N 059°52'W), 29.iv.2015, F. Zanetti, M.A.L. Santos, S.C. Emidio and P.M. Castro; 5 males, 8 females, INPA 2441, mun. Caroebe, sítio Sumaúma, rio Caroebe (00°50'N 059°42'W), 03.ii.2015, F. Zanetti, M.A.L. Santos, I.R. Almeida and S.C. Emidio; 4 males, 2 females, INPA 2432, mun. Caroebe, rio Jatapú, Entre Rios (00°45'N 059°17'W), 02.ii.2015, F. Zanetti, M.A.L. Santos, I.R. Almeida and S.C. Emidio; 2 males (57.6:34.8; 49.5:30.4), 1 female (69.5:41.6), INPA 2411, mun. São Luiz do Anauá, rio dos Peixes, fazenda Água Limpa (00°41'N 060°11'W), 05.ii.2015, F. Zanetti, M.A.L. Santos, I.R. Almeida and S.C. Emidio; 2 immat. males, 4 immat. females, INPA 2438, mun. Caroebe, vicinal 35, igarapé Taboca (00°35'N 059°43'W), 03.ii.2015, F. Zanetti, M.A.L. Santos, I.R. Almeida and S.C. Emidio.

Distribution. Guyana, Suriname, French Guyana, Brazil (Amapá, Amazonas, Pará, Roraima) (Holthuis, 1959; 1993; Rodriguez, 1982; Magalhães, 1986; 2003; Vieira, 2008; this study).

Remarks. The G1s of the specimens studied herein from the Tacutu River (Fig. 1H) exhibit an overall resemblance with the G1 of the specimen from the Surumu River figured by Magalhães (1986: 629, fig. 8). However, some of the specimens from the Jatapu River basin, in southeastern Roraima have a G1 with more longitudinally straight apical plate, resembling those from the Uatumã River basin (Magalhães, 1986: 629, figs. 9, 10).

The species has a broad distribution that includes several rivers draining both slopes of the Guyana Shield in Brazil (east from the Branco River basin in Roraima to the western portion of the state of Amapá), Guyana, Suriname and French Guiana (Holthuis, 1959; 1993; Rodriguez, 1982; Magalhães, 1986; 2003; Vieira, 2008; this study). The species is typically found in the upper course of the rivers, usually inhabiting fast flowing, lotic waters with rocky bottoms of rapids and falls (Magalhães, 1986, 2003; Holthuis, 1993).

Trichodactylidae H. Milne Edwards, 1853

Genus *Moreirocarcinus* Magalhães and Türkay, 1996

Moreirocarcinus laevifrons (Moreira, 1901) (Figs. 2A, 5)

Material examined. BRAZIL, Roraima: 6 males, 4 females, MIRR 7, mun. Caracaraí, PARNA Viruá (01°42'25"N 061°10'24"W), 28.vii.2006, L.F.R. Guterres and P.M. Castro; 1 male, 1 female, MIRR 4, idem locality, 5.iii.2006, L.F.R. Guterres and P.M. Castro; 5 males, MIRR 23, mun. Caracaraí, Perdida road, igarapé Bueiro, 01°25'16"N 060°59'17"W, 21.v.2007, L.F.R. Guterres and P.M. Castro; 1 male (20.6:16.4), INPA 1760, mun. Caracaraí, PARNA Viruá, igarapé Espelho, 01°21'51.8"N 060°58'54.2"W, 11.iv.2007, L. Rapp Py-Daniel; 1 male (16.7:13.2), 4 females (16.7:12.9–23.0:17.6), 2 male abdomens with gonopods, INPA 1904, mun. Caracaraí, PARNA Viruá, Pallial track, 01°14'36"N 061°17'29"W, 24.v.2007, T. Carvallis and F.A.D. Esteves; 2 males (24.4:19.0; 24.6:18.6), INPA 1493, mun. Caracaraí, rio Anauá, igarapé Defrente, 00°59'56"N 061°06'16"W, 24.ix.2006, L. Rapp Py-Daniel.

Distribution. Venezuela, Colombia, Brazil (Amazonas, Roraima [new record]) (Magalhães, 2003; Campos, 2002; 2005; 2014; this study).

Remarks. This species is easily recognized by the orbicular carapace with lateral margins bearing 7–8 acute teeth and frontal margin bilobed, smooth. The G1 is slender, distally straight and regularly tapering. The apex is narrow and assymetrical, with its mesio-distal border being slightly shorter than the latero-distal border (Fig. 2A).

The species is mainly distributed in the Amazon River and Orinoco River basins in Brazil, Colombia, and Venezuela (Magalhães, 2003; Campos, 2002; 2005; 2014). In the Brazilian territory, it was only known in the state of Amazonas, in the Negro River basin (Magalhães, 2003). The above records show that it also occurs in the Branco River basin and constitute the first report of the species in the state of Roraima (Fig. 5).

***Poppiana dentata* (Randall, 1840)**
(Figs. 2B, 5)

Previous records. Magalhães (2003: 230, fig. 124, in map); Magalhães and Pereira (2007: 124, in table 4 - listed under Negro River basin); Magalhães and Türkay (2008: 198).

Material examined. BRAZIL, Roraima: 4 juv. males (11.3:9.3–17.3:14.0), 2 juv. females (11.7:9.9; 13.2:10.7), INPA 1251, mun. Amajarí, rio Uraricoera, ilha de Maracá (03°21'07"N 061°25'22"W), igarapé unnamed, 5.vii.1995, V. Kowalcuk; 1 male (32.4:26.3), INPA 1896, mun. Amajarí, rio Uraricoera, Maracá Ecological Station (03°21'07"N 061°25'22"W), 14.iii.2008, leg. unknown; 1 male (21.3:17.7), INPA 2412, mun. Amajarí, rio Uraricoera, Maracá Ecological Station, 03°21'13.6"N 061°29'45.0"W, 4.vi.2008, coll. unknown; 2 males (30.0:24.4; 41.9:33.2), 2 females (33.1:26.3; 38.8:30.7), MIRR 10, mun. Bonfim, igarapé Fogo, vila Vilhena (03°21'01"N 059°52'41"W), 6.viii.2006, D. Coscarelli; 1 male (28.0:22.4; 30.7:23.2), MIRR 102, mun. Mucajá, rio Mucajá, vicinal Lago, vila Tamandaré, (02°34'53"N 060°58'00"W), 4.ix.2011, F. Zanetti, T.E. Sousa and S.C. Emidio; 1 male (46.7:37.3), MNRJ 8711, rio Mucajá (02°26'13"N 060°52'10"W), 19–21.ix.1986, C.F.S. Menezes.

Distribution. Nicaragua, Trinidad, Venezuela, Guyana, Suriname, French Guiana, Colombia, Brazil (Roraima, Amazonas) (Magalhães, 2003; Magalhães and Türkay, 2008; Campos, 2005; 2014; Pereira and García, 2006; this study).

Remarks. With respect to the carapace morphology, *P. dentata* highly resembles *M. laevifrons*. However, both species can be readily distinguished by the spined (in *P. dentata*) or smooth (*M. laevifrons*) frontal margin. The morphology of the G1 of the specimens studied herein (Fig. 2B) is very similar to the description and illustrations offered by Magalhães and Türkay (2008).

Poppiana dentata has a very wide distribution in northern South America, occurring in the Orinoco River basin and in several coastal river basins from French Guiana to Colombia, as well as on the island of Trinidad and in Nicaragua (Campos, 2005; 2014; Magalhães and Türkay, 2008). The distribution of the species in the Amazon River basin seems to be

restricted to the Branco River basin, in Roraima (Fig. 5), and the upper Negro River basin, in Amazonas (Magalhães and Türkay, 2008; this study).

***Sylviocarcinus pictus* (H. Milne Edwards, 1853)**
(Figs. 2C, 6)

Previous records. Magalhães and Türkay (1996b: 117, fig. 38, in map); Magalhães (1998: 520, in catalogue); Magalhães (2003: 244, fig. 134, in map); Magalhães and Pereira (2007: 124, in table 4 - listed under Negro River basin); Castro and Silva (2013: 42, in table 1).

Material examined. BRAZIL, Roraima: 1 male, INPA 2425, mun. Amajarí, rio Ereú, 04°02'N 061°23'W, 16.iv.2014, F. Zanetti and M.A.L. Santos; 2 females, INPA 1901, mun. bank of rio Jauaperi, 00°31'N 060°27'W, 29.iv.2015, F. Zanetti, M.A.L. Santos, S.C. Emidio and P.M. Castro; 6 males, 4 females, INPA 2423, mun. Caracaraí, paraná Preguiça, lower rio Branco, 00°29'N 061°39'W, 27.iii.2014, F. Zanetti and M.A.L. Santos.

Distribution. Venezuela, Guyana, French Guiana, Colombia, Peru, Bolivia, Brazil (Amapá, Amazonas, Pará, Maranhão, Piauí, Rondônia, Roraima) (Magalhães and Türkay, 1996b; Mora-Day *et al.*, 2008). Additional records of the species in the state of Roraima were presented by Magalhães and Türkay (1996) from the Surumu and Branco Rivers.

Remarks. The G1s of the specimens studied herein (Fig. 2C) are morphological highly similar to the G1 described and illustrated by Magalhães and Türkay (1996b).

Sylviocarcinus pictus is one of the most common and widespread species of Trichodactylidae, occurring in the Amazon River basin and in coastal river basins of northern South America, in Venezuela, Guyana and French Guiana (Magalhães and Türkay, 1996b; Mora-Day *et al.*, 2008). It is also broadly distributed in Roraima (Fig. 6). The species has been recorded from both slopes of the Serra Pacaraima and Serra Acari, with occurrences in the Cuyuni River (Mora-Day *et al.*, 2008), Rupununi River (Magalhães and Türkay, 1996b), and upper Essequibo River (Lasso *et al.*, 2008) basins on the Venezuelan and Guyanan sides, and in the Branco River and Jauaperi River, Uatumã River and Trombetas River basins (Magalhães and Türkay, 1996b; this study) on the Brazilian side. However, it does not occur in tributaries of the Orinoco River with headwaters in the Guyana Shield as suggested by its absence in surveys recently done in some river basins of this region (Magalhães and Pereira, 2003; Pereira and García, 2006; Mora-Day and Blanco-Belmonte, 2008; Mora-Day *et al.*, 2008).

Genus *Valdivia* White, 1847

Valdivia serrata White, 1847 (Figs. 2D, 7)

Previous records. Castro and Silva (2013: 42, in table 1).

Material examined. Distribution. Venezuela, Suriname, Ecuador, Peru, Colombia, Brazil (Acre, Amazonas, Maranhão, Pará, Rondônia, Roraima), Bolívia (Holthuis, 1959; Rodríguez, 1992; Magalhães, 2002; 2003; 2005; Vieira, 2008; Castro and Silva, 2013; Campos, 2014; this study).

Remarks. The taxonomic status of *V. serrata* and related forms (Magalhães and Türkay, 1996a) is not yet settled due to a considerable amount of variability

found either in somatic or gonopodal characters (C. Magalhães, unpubl. data). Most of the male specimens studied herein are immature or subadults. As such, the gonopod morphology could not be adequately evaluated. However, in the few fully-grown adults examined, the G1 shows the distal portin moderately curved (approximately 40–45°) in ventro-lateral direction, with its margins nearly subparallel; the subterminal field of spines is well developed and the ventral border has a distinct subretangular, median lobe (Fig. 2D).

The present species has a very broad distribution throughout the entire Amazon River and Orinoco River basins as well as in the coastal river basins of northern South America, but has only recently been reported in the state of Roraima (Castro and Silva, 2013). The above records show that it is also well distributed in the state, occurring mainly in the lowland portion of the Branco River, Jauaperi River and Jatapu River basins (Fig. 7).

DISCUSSION

All ten species of freshwater crabs that are reported herein from the state of Roraima are distributed in the Branco River basin, although *K. latifrons*, *S. pictus* and *V. serrata* can also occur in the Jauaperi River and Jatapu River basins (Figs. 3–7). The pseudothelphusid species are usually associated with rivers originating in the mountainous regions along the border with Venezuela and Guyana in the northwestern (Serra Paraima), northern and northeastern (Serra Pacaraima), and the southeastern portion of the state (Serra Acarái) (Figs. 3–4), although *F. stenolobus* can also be found in lower regions along the upper Branco River (Fig. 4). On the other hand, the trichodactylid species are mainly distributed in lower elevation areas along the Branco River and its tributaries, Uraricoera River and Tacutu River (Figs. 5–7), but *S. pictus* can also occur at higher elevations such as in some tributaries of the Uraricoera River coming from the Serra Pacaraima (Fig. 6). This general altitudinal distribution of representatives of both families in Roraima is in accordance with the zoogeographic division of the Neotropical freshwater decapod fauna mentioned by Rodriguez (1981).

Pseudothelphusidae is slightly richer in species than Trichodactylidae (six vs four) in Roraima, but these numbers may be somewhat underestimated for

both families. The more elevated regions along the mountainous areas in the northern and western part of the state are either protected areas or indigenous reserves (EPE, 2010), which makes biological surveys more difficult to conduct in these areas. As a mountainous group, the number of pseudothelphusids might be greater considering that large portions of this territory have not yet been sufficiently explored for decapods. For instance, *Kunziana irengis* (Pretzmann, 1971) occurs in Guyana along the Ireng River and upper Potaro River basins (Magalhães et al., 2009). The Ireng River marks the border between Brazil and Guyana (it is named Maú River on the Brazilian side) and its presence in the northeastern part of the state of Roraima would not be unlikely. Provided they are properly surveyed, some other regions of the state may potentially increase the number of crab species in Roraima as well. This is the case, for instance, in the Serra da Mocidade, which comprises a mountainous complex with up to 1700 m in elevation, isolated from the Guyana Shield, in the center-western portion of the state. The potential of these isolated mountainous areas in the Amazon region to reveal new pseudothelphusid crabs is high, as indicated by the description of *Microthelphusa lipkei* Magalhães, 2010 from Serra do Aracá (Magalhães, 2010), also a group of isolated mountains situated in the state of Amazonas close to the border with Roraima, a little to the west of the Serra da Mocidade.

The number of trichodactylid species from Roraima may also be somewhat underestimated. Extensive lowland areas of the lower Branco River are still poorly explored for freshwater crabs (Figs. 5–7). Magalhães and Pereira (2007) listed eight species as occurring in the Negro River, of which the Branco River is the main tributary, and four of them (*M. laevifrons*, *P. dentata*, *S. pictus*, *V. serrata*) are also recorded from Roraima henceforth. It would not be unexpected that at least some of the others could also be found in the lower Branco River if more intensive surveys of the area were carried out.

As expected, the species richness of freshwater crabs of the Branco River is lower than that of Negro River, which has a much larger drainage surface and is better surveyed, especially in its lower course. Magalhães and Pereira (2007) listed 10 pseudothelphusids and eight trichodactylids from the Negro River basin, while six and four, respectively, are herein reported from the

Branco River basin. In total, the species richness of crab of the Xingu River basin is higher than that of the Branco River basin (13 vs. 10 species, respectively), but Branco River basin crab fauna is a little richer in pseudothelphusids than Xingu River basin fauna (six vs. five species, respectively). However, Xingu River has more trichodactylids than the Branco River (eight vs four, respectively) (Magalhães et al., unpubl. data). When comparing the total number of species compiled by Magalhães and Pereira (2007) to the sub-basins of the other northern tributaries of the Amazon basin draining the Guyana Shield, the Branco River basin shows higher species richness (Uatumã River: six species; Trombetas River: seven species; Jari River: four species). However, such comparisons should be made with great care as these river basins are very poorly surveyed for decapods.

ACKNOWLEDGEMENTS

The authors dedicate this contribution to Prof. Dr. Ludwig Buckup (Universidade Federal do Rio Grande do Sul, retired) in recognition of his distinguished career as a zoologist and particularly for his achievements that have greatly contributed to the development of the Brazilian Carcinology both scientifically and in the formation of young scientists. PMC also thanks CNPq for the Research Project 35.0413/2005-3-DCR/CNPq/FEMACT; FZ and PMC thank the Acordo de Cooperação Técnico-Científica 01280.000370/2011 between INPA, UERR, and IACTI-RR that allowed the accomplishment of the present work. CM thanks the Conselho Nacional de Desenvolvimento Científico e Tecnológico – CNPq for an ongoing Research Scholarship 304736/2015-5, as well as Victor Py-Daniel, Ulysses C. Barbosa, and Jansen Zuanon for making the specimens from their collections in Roraima available to this study. The authors are grateful to Douglas Bastos and Priscila Madoka Ito for their kind help with the QGIS software, Colleen M. Flanagan for reviewing the English wording, and two anonymous reviewers for their comments.
